

EANTC Independent Test Report

Huawei WDM Compatibility Test OptiXtrans E6608 April 2022

Introduction

Huawei commissioned EANTC to validate functional, interoperability, and performance aspects of the Huawei OptiXtrans E6608 wave division multiplex (WDM) solution, focusing on the Storage Area Network (SAN) use case scenarios.

We conducted the test in Huawei lab in Cheng Du, China, in November 2021.

Huawei OptiXtrans E6608 is an optical-electrical WDM transmission device. Huawei OptiX OSN 1800 II Pro is a product of the same brand. Both devices provide the same implementation. It is designed for enterprise DCI use case scenarios—any situation where two redundant data centers are located in a region within a few kilometers distance (up to 100km).

In this test, EANTC verified the real enterprise case to ensure that the test results were consistent in this series of tests. The real enterprise case included two emulated data centers for the following use cases focused on Fibre Channel (FC). There is usually packet data traffic (Ethernet-/IP-based) and storage traffic forwarded over the wide-area link in a WDM DCI scenario.

Executive Summary

We verified the interface-speed forwarding of Huawei OptiXtrans E6608 on the FC port side and the longdistance forwarding between the two simulated data centers. We tested the forwarding performance when a quorum server synchronized data traffic between both emulated data centers. We verified the compatibility of its board types LDCA and LTX to the FC-PI-6, FC-PI-3, and FC-PI-5 standards.

The test bed consisted of emulated data centers integrated with 3rd party Fibre Channel switches of different vendors represented by Brocade and Cisco, using hybrid switch pairs of Brocade G620 / Brocade G620, Brocade G620 / Brocade 6505, and Cisco MDS 9148S/ Cisco MDS 9148S.

Test Highlights

- → DCI interoperability with multiple Fibre Channel switches, including the combination of Brocade G620-G620, G620-6505, and Cisco MDS 9148S -9148S
- → Compatibility certification with three types of Fibre Channel Physical Interface (FC-PI), including FC-PI-3, FC-PI-5, and FC-PI-6¹
- → Transparent multi-switch type forwarding between Brocade 6505 and Brocade G620
- → Stability of overnight soak testing
- → Protection against Inter-Switch Link (ISL) failure, ISL trunking and long haul link failure
- → Capacity measurement to link speeds of 8G, 10G, 16G, 32G with up to 100 km long haul connections²

We verified the robustness of the DUT by performing administrative activities on the DUT and connected equipment, as well as ISL trunking and protection against long-haul link failure. We also put DUT under continuous load for 24 hours in a soak test environment to make sure it would support uninterrupted service. The system remained stable without any restart or service interruption, zero packet loss, and low latency, as expected. Finally, we measured the latency introduced by the OptiXtrans E6608. It matched the expectations based on switching delay and physical distance.

¹ FC-PIs specifications are defined by the T11 Committee of the International Committee on Information Technology Standards (INCITS). INCITS is accredited by and operates under rules approved by the American National Standards Institute (ANSI). FC-PI-6 (ANSI INCITS 512-2015) defines the standard to support the link speeds of 32G, 16G, and 8G; FC-PI-5 (ANSI INCITS 479-2011) defines the standard to support the link speeds of 16G, 8G, and 4G; FC-PI-3 (ANSI/INCITS 460-2011) defines the standard to support the link speeds of 10G, 4G, 2G, and 1G.

² Cisco MDS 9148S was tested with 40 km long-haul at FC8G and no 24-hour stability test

Device Under Test

Huawei explained that the OptiXtrans E6608 is designed for DCI and ready for simplified deployment, ultrabroadband and high integration data traffic.

| FC-PI-3 | FC-PI-3 | | | |
| Table 2: Optical Transceivers | | | | |

between FC Switch and DUT

Long haul connection tests were successfully carried out across two distances:

- 100 km long haul with Brocade G620 / G620 and Brocade G620 / 6505 pairs, respectively
- 40 km⁵ calculated medium-haul with Cisco MDS 9148S pairs, respectively

³ Brocade 6505 does not support FC-PI-6 and FC-PI-3

⁴ Cisco MDS 9148S does not support FC-PI-3 and FC-PI-6

⁵ Due to Cisco MDS 9148S buffer limitation, we can only test up to 40 km.

Testbed Description

The Huawei OptiXtrans E6608 and OptiX OSN 1800 II Pro were the device under test (DUTs) respectively. They have the same hardware, and only the product name is different for a different market. Therefore, we designed the test bed as shown in the figure below.

Huawei installed SUSE Enterprise Linux 12.4 in a bare metal mode on both hosts. We used vdbench already installed at Huawei labs by Huawei engineers to generate FC traffic. The host has 2x Intel® Xeon® E5-2658 v4 @2.30GHz CPUs, 8x 16G DDR4 memory, 1 x Huawei IN300 (2x FC32G) port FC Host Adapter (HBA), 1 x Emulex LPe16002B-M6 PCIe 2-port 16Gb Fibre Channel Adapter and 1x SAS 800G SSD. We used all the CPU, FC adapter ports, and 16G memory for our test. The storage hardware included two Huawei Ocean-Stor 5000 V3 (referred to as Huawei OceanStor) devices, each equipped with 24 Non-Volatile Memory Express (NVMe) Solid-State Drive (SSD) disks that provided up to 5.8 GB/s (Gigabytes per second) Input/Output traffic. Using the open source test tool Vdbench released by Oracle, we generated bidirectional baseline traffic at the full configured speed.

The key point from the topology was the quorum server in place. It means that the storage system also had redundancy control. The quorum server recognized one of the Huawei OceanStor 5000 V3 as preferred storage and another one as non-preferred storage. The quorum server's strategy was to keep the preferred storage in a working state when a link or storage failure is detected.

EANTC-

Test Results

Capacity Testing

We measured the maximum FC-interface forwarding of the DUT using FC read block traffic (reading block size 32KiB) generated respectively between emulated data centers.

The following tables show the throughput. We performed a capacity test for each of the board under test, with all three setups, respectively. Each traffic

| Setup | Speed Ty- pe | Expected Throughput (MB/s) ⁷ | Measured Throughput, per direc- tion (MB/s) | | Verdict |
|------------------------------|-----------------|--|--|--------------------------|---------|
| | | | LDCA | LTX | |
| 1. Brocade G620 | FC800 | 800 | 781 | 781 | Pass |
| pair | FC1200 | 1200 | 1172 | 1168-1171 | Pass |
| | FC1600 | 1600 | 1558 | 1560-1561 | Pass |
| | FC3200 | 3200 | 3113-3117 | 3113-3115 | Pass |
| 2. Brocade G620/6505 pair | FC1600 | 1600 | 6505: 1529 G620: 1558 | 6505: 1531 G620: 1563 | Pass |
| 3. Cisco MDS 9148S/9148S | FC800 | 800 | 778 | 777 | Pass |

Table 5: LDCA and LTX Interface Throughput

stream carried bi-directional traffic.

⁷ The expected throughput is based on the layer 2 payload; we used a ratio of 97% of the link speed. The ratio is based on the formula: 2,048 bytes payload size / 2,112 bytes maximum frame size * 100%, which excludes overhead from the throughput consisting of Start Of Frame (SOF), Cyclic Redundancy Check (CRC), and End of Frame (EOF). For example, 3.104 GB/s = 97% * 3.2 GB/s link speed.

EANTC

Latency Test

We measured with the Viavi MTS5800-100G tester the WDM system's latency value. In this setup, we connected both DUTs back to back with the measurement tool (see figure), which provides latency value in microseconds' precision. We removed all data center devices from the test bed and remained only both WDM devices running the FC services between the traffic generators.

We generated FC traffic from all ports at different FC speeds consisting of 8G, 10G, 16G, and 32G. The test tool supported the latency measurement on the same port. Therefore, we designed the Rx and Tx like below. Using an optical splitter, we split the Rx and Tx

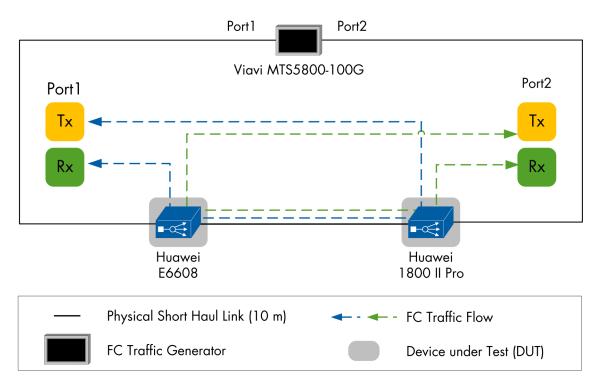

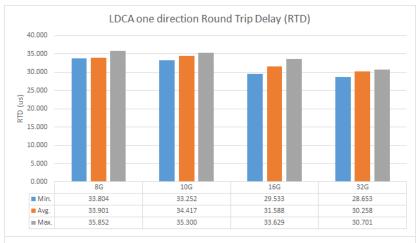

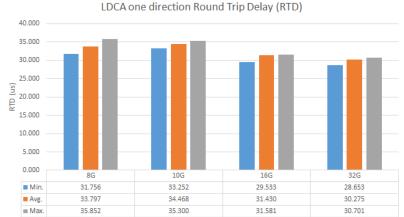

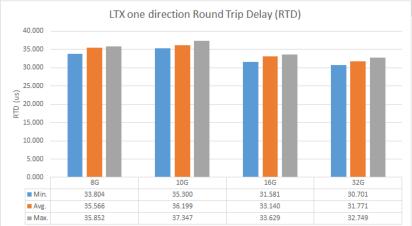

Figure 3: Latency Test Topology

at the traffic generator port into two separate fibers and connect them to the two WDM devices as shown in the figure.

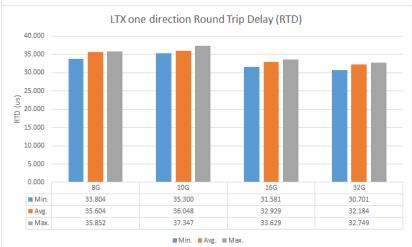

Figure 4: Latency Results of LDCA and LTX

EANTC Test Report: Huawei WDM Compatibility OptiXtrans E6608 – 8

Availability Test

We verified that the DUT maintained stability when performing administrative activities on the DUT's hardware and the FC switch connected in the test environment.

We emulated a baseline scenario where the host's I/O traffic flowed between SANs from two different emulated data centers under normal conditions. The host on each side of the DCI initiated I/O operations, and the To verify the stability of the DUT, we emulated a common set of failures of the DCI segment while the traffic was running under normal conditions. These were a total of 7 types of emulated failures as shown in the figure.

In ISL trunking and long-haul link protection, we ex-

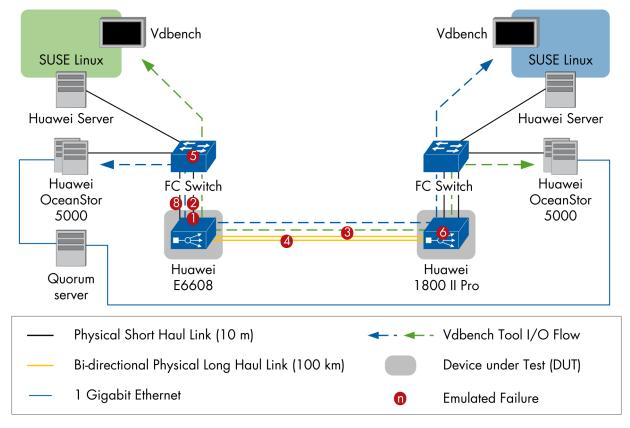

Figure 5⁸: Emulated Failure in the Test Bed

target was the storage on the other side of the DCI. The following figure depicts the main traffic streams (blue and green, both bidirectional) between the emulated data centers. pected the DUT to provide traffic switching between primary and redundant links. Especially with the participation of Quorum servers, we expected that the active-active storage cluster to protect the traffic switching between storage devices.

⁸ The numbers in figure 5 represent the test cases in the test plan. Missing of number 7 is because 7 represents 24 hour long-haul test, and it doesn't include any failure scenario.

Active-Active Storage Switch Over

Under failure types 1, 2, 3, and 6, the test results showed the same status of the traffic that has been switched over. The primary storage obtained the I/O access of the host in the same data center and continued I/O operation. The secondary storage stopped

Huawei OceanStor 5000 V3 implements a technology called "HyperMetro" for synchronizing the states between preferred storage and non-preferred storage.

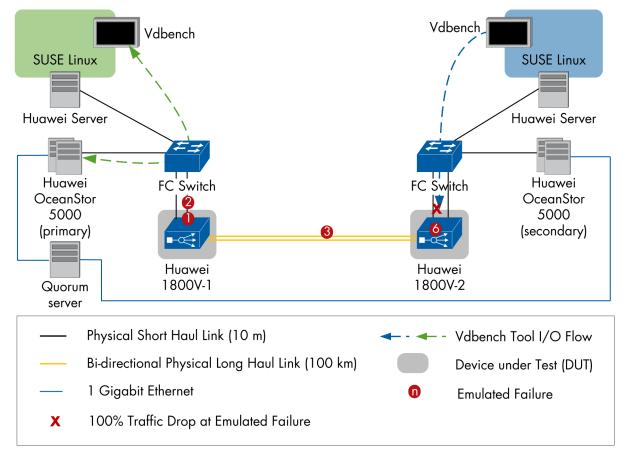

Figure 6: Traffic Status after the Switch Over for Failure Types 1, 2, 3 and 6

receiving any I/O access from the remote datacenter, neither from the local data center. The former case was because these four types of failure could interrupt the whole DCI connection from different hardware locations (see figure below), thereby causing it to stop transmitting data between both data centers. The latter phenomenon was due to the design mechanism of quorum server as described below. Once the link between two storage systems went down, the HyperMetro pair changed to the "To be synchronized" state. The Logic Unit Number (LUN) in the preferred storage continued providing service while the LUN in non-preferred storage stopped. During a link recovery, once the quiescing time (300 s) passed, we observed that the traffic switched back to baseline status between DC1 and DC2. We did not observe any impact as expected.

| No. in | Test Case | Action | Service Interr | uption | Verdict |
|--------|---|------------|-----------------------|---|---------|
| Fig. 6 | | | Expected ⁹ | Observed (for primary storage) ¹⁰ | |
| 1 | E-Port Disable/ Enable Test | Disable | 10s | A maximum of 7s service interruption time, including 5s drop to OMB/s | Pass |
| | | Enable | No impact | No impact | |
| 2 | E-Port Cable Disconnect/ Reconnect Test | Disconnect | 10s | A maximum of 7s service interruption time, including 5s drop to OMB/s | Pass |
| | | Reconnect | No impact | No impact | |
| 3 | Long Haul Network Failure without | Disconnect | 10s | A maximum of 7s service interruption time, including 5s drop to OMB/s | Pass |
| | Redundancy | Reconnect | No impact | No impact | |
| 6 | DUT Reset Test | Shut down | 10s | A maximum of 7s service interruption time, including 5s drop to OMB/s | Pass |
| | | Turn on | No impact | No impact | |

Table 6: Out of Service Overview (Active-Active Storage Cluster Protection)

⁹ The expected value included 5s fault detection by the quorum server and 15s from it to triggering an activeactive switchover. Once the quorum server detected the fault, it triggers an active-active switchover, which lasts for 15 seconds (generally within 10 seconds in lab tests). After the switchover has been complete, the preferred storage took over services.

¹⁰ We observed 5s complete traffic drop to 0 MB/s during the switch over. The Huawei team configured the quorum server with a 5s timer to detect the link heartbeat failure between the storage arrays. The link between storage arrays sent a heartbeat packet every second. After five consecutive heartbeat packets expired, the link was identified as disconnected. The 6s complete traffic drop to 0 MB/s included the time from discovery to switchover at the quorum server.

FC Switch Reboot

Once the FC switch from one data center rebooted, the storage on the remote site where the FC switch was not touched obtained the host's I/O access and continues to perform I/O operations. In the data center where the FC switch rebooted, the storage stopped receiving any data from the FC switch until the FC switch was available again. Depending on the time taken by the FC switch to become available, we observed:

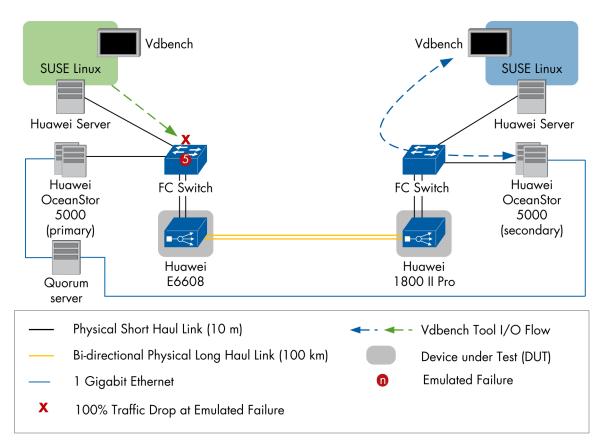

Figure 7: Traffic status during FC switch reboot

| No. in | Test | Action | Service Interru | uption | | | |
|--------------|----------|---------|------------------------|--|------|--|--|
| Fig. 7 | Case | | Expected ¹¹ | Observed (for primary storage) ¹² | | | |
| 5 | Reboot d | | 15s | A maximum of 10s service interruption time on non- reboot site, including a maximum of 8s drop to OMB/s | Pass | | |
| Test Turn | | Turn on | No impact | No impact | | | |

Table 7: Out of Service Overview (Active-Active Storage Cluster Protection)

¹¹ The expected value included 5s fault detection by the quorum server and 15s from it to triggering an activeactive switchover.

¹² The 8s drop to OMB/s included 6s of switch over by the quorum server and the reboot time of the switch (during the reboot process, the link at the FC switch was interrupted from time to time)

EANTC Test Report: Huawei WDM Compatibility OptiXtrans E6608 – 12

The Brocade G620 pair rebooted less than 1 min. The FC service did not fully interrupt from the reboot site. The reboot site traffic was redirected to the nonreboot site and kept working, whereas the nonreboot site switched to access the local storage as well. There was around 40-50 s service interruption time (including a maximum of 39s drop to OMB/s).

After the FC switch completed the reboot and the quiescing time (300s) passed, we observed that the traffic switched back to the initial status between DC1 and DC2. We did not observe any impact as expected.

Long Haul Link Protection

We measured the switch-over time for the system under test to switch traffic to the backup link when the primary long-haul link fails. While traffic was running, we connection between both WDM devices. We observed that the traffic was switched to the backup link. The following Table shows the switch-over time measured. No session drops appeared during this time.

When we reconnected the primary link previously disconnected, we did not observe any impact on the traffic. Then we disconnect the protect link again. The WDM switched back to the primary link again with the switch over time. The last step is to reconnect the protected link. We observed no impact on I/O flow traffic.

ISL trunking is a resiliency technology that Brocade uses to improve performance and redundancy. When two E-ports have the exact same configuration and are in the same zone, these two E-ports can be seen as a bundle. It has the load-share function that the two ports can achieve double throughput of the configured speed. They are also back-up for each other when one

| No. in | No. in Fig. 5 Test Case Setup Action Service Interruption Expected ¹³ Observed | | uption | Verdict | | |
|--------------------|--|-------------------------|------------|------------------------|---|------|

Table 8: Out of Service Overview

disconnected the primary link from the long-haul

¹³ Includes the impact of end-to-end flow control (a total of four hops from the host to the storage through two FC switches). With credit recovery enabled on the FC switch, we calculated each hop for 1 second interruption, based on the hold off time of 500ms (milliseconds that a frame could be buffered on a port without being overwritten) configured on the Brocade G620 switch; added to that the impact of retransmission caused by the frame loss during the link failure, and vdbench accuracy of 1 sample per second.

¹⁴ The expected value includes 4s of impact by end-to-end flow control (see explanation as provided in * note), plus 2s of impact by edge hold off time (EHT) on F port. Note, the value is not provided by Brocade 300 manual, we calculated a double theoretical value of 250ms for FC1G and FC2G (250ms is the default EHT value of FC16G), so added 1s per F port (based on 1 sample/sec based on vdbench).

| Board Under Test | Switch Over Time (s) |
|------------------|--|
| LDCA | A maximum of 3s service interruption (including a maximum of 1s drop to OMB/s) |
| LTX | A maximum of 3s service interruption (including a maximum of 1s drop to OMB/s) |

Table 9: Switch Over Time Brocade G620 - G620

| Board Under Test | Switch Over Time (s) | | | |
|------------------|--|--|--|--|
| LDCA | A maximum of 3s service interruption (including a maximum of 1s drop to OMB/s) | | | |
| LTX | A maximum of 3s service interruption (including a maximum of 1s drop to OMB/s) | | | |

Table 10: Switch Over Time Brocade G620 - 6505

link has a problem or is down for unknown reasons. In our test, the ISL trunking was up and running at the beginning of the test. We unplugged fiber from one of the trunking ports, and we expected the traffic to reduce to 50% but no interruption. We then plugged the fiber back to its original port, and we expect the traffic to increase by 100%.

Summary of Test Runs for All Failure Scenarios

| Board Under Test/ | E-port Interface used in Test Case | | | | | | |
|-------------------|------------------------------------|----------|---------|----------|---------|-----|----------|

With all boards under test, the DUT demonstrated its ability to maintain stability while performing the above failure scenarios in each of the test setups.

Soak 24 Hours Test

We verified the WDM system's reliability in terms of performance consistency under long-period stress load conditions. The Huawei team configured all three boards in a snake configuration, keeping traffic flowing between the two data centers.

We used the maximum load of the baseline traffic for each of the selected interfaces as measured in capaci-

ty tests and formed 36 combinations as listed in the tables below.

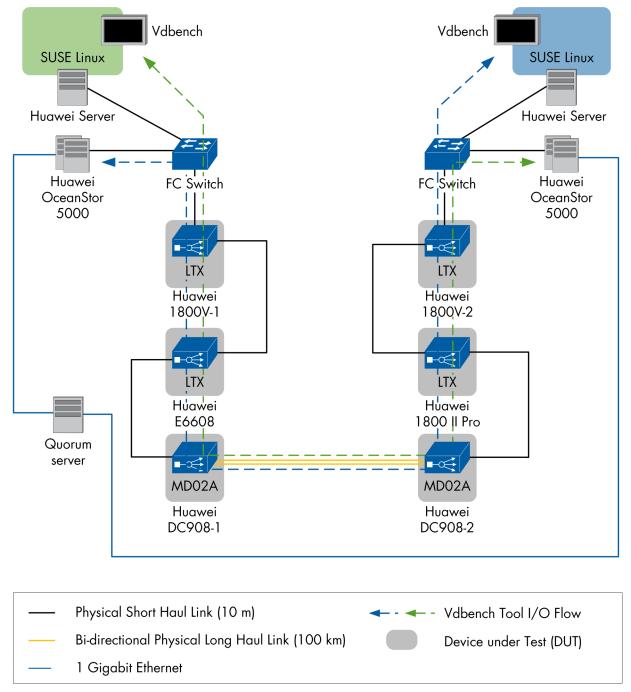

Figure 9: 24-hour Throughput Topology of LTX

The test tool Vdbench triggered the baseline traffic bidirectional for 24 hours. During that time, we monitored the system log of both hardware and software. We confirm that the system could transfer the data at a consistent rate and constant latency of 24 hours. As expected, the system under test remained stable; we did not observe any software crashes or hardware failures during the test duration.

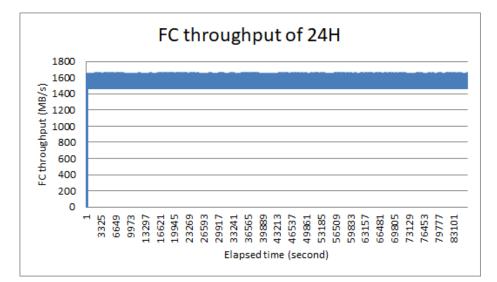

Figure 10: 24-hour Throughput of LDCA at FC 16G

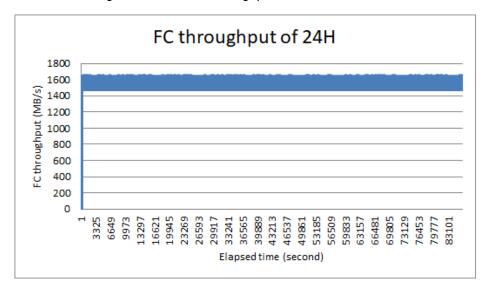

Figure 11: 24-hour Throughput of LTX at FC 16G

Brocade (G620/G620, G620/6505) and Cisco (MDS 9148S/9148S). Multiple optical transceiver functions were certified in the E_port between these FC switches and the Huawei OptiXtrans E6608, including FC-PI-6, FC-PI-5, and FC-PI-3.

EANTC validated forwarding speeds in FC 8G, 10G, 16G, and 32G scenarios. When forwarding traffic at any of these standardized speeds, the Huawei OptiXtrans E6608 did not exhibit any speed impact. The extended 24 hours soak testing confirmed stable operations of OptiXtrans E6608 without any traffic impact.

Conclusion

We verified interoperability of Huawei OptiXtrans E6608 and third-party Fibre Channel switches from
